

SURU PRESENTATION:

Updated Constraints

On Asteroid-Mass Primordial Black Holes

Presenter: Samuel English

Why Does Dark Matter (DM) Matter?

Breakdown of Energy Density of Universe & Composition of Matter

Matter Makeup Only:

Discrepancies in Velocity

Why We Postulate the Existence of Non-luminous Matter

Primordial Black Holes (PBHs) as DM Candidates

& Microlensing Event Detection

Origin of PBHs

Hypothetical black hole type formed in early universe

Cosmic inflation period generated patches of overdensity (quantum fluctuations)

Does not rely on existence of exotic particles

Detection of PBHs

Gravitational wave detection (LIGO, VIRGO)

Gravitational lensing events

Finite Size Effects

Regime in which FSEs take over:

When the Einstein radii of the PBHs becomes \leq size of source star

Corrections to constraints become larger as stellar sizes become significant for low mass range of PBHs

$$\frac{\theta_S}{\theta_E} = \frac{R_S d_L}{R_E d_S} = R_S \left(\frac{x}{1-x} \right)^{1/2}, \quad (11)$$

The finite size effects also weaken the constraints for intermediate mass black holes. The finite size effects are greatest when the lensing PBH is close to the source star. That is, as d_L approaches d_S , the finite size effect washes out magnification for all masses of PBH. This is also the region where the DM density contribution from M31 in Eq. (10) is the greatest, leading to a noticeable weakening of the constraints for all but the high mass region of the relevant parameter space.

Subaru/HSC Constraints on PBH Microlensing ?

Microlensing constraints on primordial black holes with the Subaru/HSC Andromeda observation

5. DISCUSSION

RGB stars have much greater radius than that of main sequence stars, where the finite source size effect is more significant. Here we employ a solar radius ($R_{\odot} \simeq 6.96 \times 10^{10}$ cm) for all source stars for simplicity, assuming that the upper bound is mainly from the microlensing for main sequence stars, rather than for RGB stars [31]. We followed [37] to re-estimate the event rates of PBHs microlensing taking into account the finite source size effect. Fig. [24] shows that the finite source size effect lowers the event rate, compared to Fig. [8]. In particular the effect is greater for PBHs of smaller mass scales and in the M31 halo region.

Oversimplification, assumption was incorrect.

Modeling Andromeda's (M31) Population of Stars

Obtaining Radii from Luminosities & Temperatures

Take data from PHAT
(Panchromatic Hubble
Andromeda Treasury) survey,
available publicly online

Select individual stars which meet
threshold criteria, allowing us to
subsequently manipulate data
values

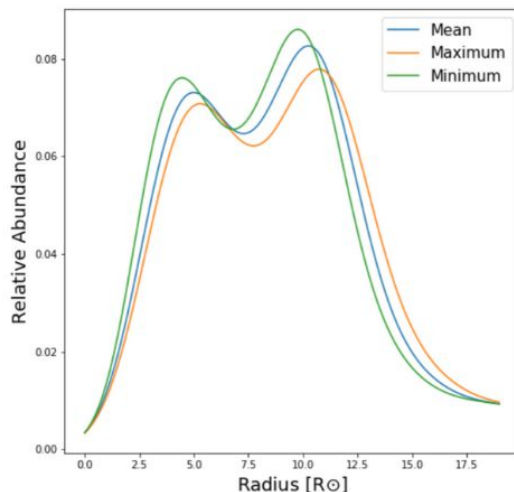

Compare to synthetic star
catalogue (MIST): obtain
histogram of stellar population
distribution

Stellar Population Distribution of M31

& Subsequent “Event Rate” Findings

Binned distribution for size of stars contributing to HSC constraints on PBH

Population of stars in M31 which could have microlensing light curves resolvable by HSC survey

Constraints for example individual radii of a source star

Differential Event Rate

for microlensing of a single star by a PBH:

IT'S NOT MAGIC, IT'S CALCULUS!

$$\frac{d\Gamma_{PBH}}{d\hat{t}} = 2 \frac{\Omega_{PBH}}{\Omega_{DM}} \int_0^{d_s} dd_L \int_0^{U_T} du_{min} \quad (10)$$
$$\frac{1}{\sqrt{u_T^2 - u_{min}^2}} \frac{\rho_{DM}(d_L)}{M_{PBH} v_c^2(d_L)} v^4 \exp \left[- \frac{v^2}{v_c^2(d_L)} \right],$$

Density(PBH/DM) vs. Mass(PBH)
